

Documentation & Submission

Dataset Used

Multiple datasets were used to build the dashboard, including Customer, Product, Store, and Transaction tables. Each dataset contains different types of information such as customer demographics, product details, store locations, and sales transactions. Using multiple datasets helped in performing detailed analysis across customers, products, stores, and regions instead of relying on a single table.

Data Cleaning

Basic data cleaning was performed before analysis. Blank rows and unnecessary columns were removed, and column names were standardized for consistency. All datasets were converted into Excel table format to improve data handling. Data types were verified to ensure that ID fields and numeric values such as sales and quantity were correctly formatted for calculations and relationships.

Formulas

Instead of using only manual formulas, PivotTables and the Excel Data Model were extensively used for calculations. Aggregation functions such as SUM and COUNT were applied to calculate Total Sales, Total Quantity Sold, and Total Customers. Using PivotTables reduced formula complexity while ensuring accurate and dynamic calculations across multiple datasets.

Key Insights

By analyzing multiple datasets together, the dashboard revealed clear patterns in sales performance. Certain regions and cities contribute more to total sales, while specific product categories and top products drive most of the revenue. Sales and quantity trends vary across regions and customer segments, helping to understand demand behavior and business performance more effectively.

DASHBOARD PREVIEW

Final Dashboard Screenshot

The above image shows the final one-page interactive retail sales dashboard created using Excel. The dashboard includes key performance indicators, charts, and slicers that provide insights into sales performance, customer behavior, and product trends. Interactive filters allow users to dynamically explore data across regions, cities, products, and categories.
